Tutorial 3 : Developing systems by refinement Dominique Méry 25 octobre 2025

Exercice 1 ggx1-tut3

We consider the following Event-B machine and the machine is parametrized by the assertion I(x) which is the invariant. The questions will consider several cases for the invariant I(x).

```
EVENT evt2
                                             WHEN
MACHINE QUESTION
                                             grd1: x \le -1
VARIABLES
                                             grd2: x \ge -37
                                             THEN
INVARIANTS
                                             act1: x := x-1
                                             END
  I(x)
                                             EVENT evt3
EVENTS
EVENT INITIALISATION
                                             WHEN
                                             grd1: x \leq -2
 BEGIN
 act1:x:=-12
                                             grd2: x \ge -4
 END
                                             THEN
  EVENT evt1
                                             act1: x := x-1
  WHEN
                                             END
                                             EVENT evt4
 grd1: x \ge -6
                                             WHEN
 THEN
                                             grd1: x \le -15
 act1: x := x{+}1
 END
                                             THEN
END
                                             act1: x := x+1
                                             END
                                           END
```

We consider several cases for defining the invariant and we have to consider the correctness of the proposed invariant. For every question, you should check that the assertion is either an invariant or a theorem or neither an ibvariant nor a theorem.

You can use the Rodin platform or you can use a formal justification.

Question 1.4 Propose an invariant I(x) which is exactly characterizing the set of reachable states of the machine QUESTION or equivalently, the strongest invariant for the machine QUESTION. Explain why it is the strongest invariant of the machine QUESTION. The property to be the strongest invariant means that if J(x) is another invariant, then $I(x) \Rightarrow J(x)$.

Question 1.5 In the last question, you derive an invariant I(x) but now you should prove or disprove that the model QUESTION is deadlock-free.

Exercice 2 ggx2-tut3

We consider the general problem of access control with the administration of access rights.

- 1. Model the access control problem in the case of the access of persons in buildings. We assume that the rights are given and are not modified.
- 2. Model the access control problem by adding specific actions for administrating access rights.
